

# VUV AND EUV IRRADIATION OF $\text{CH}_4 + \text{NH}_3$ ICE MIXTURES

Lily Leung

# Contents

## ■ Motivation

## ■ Methodology

- Experimental setup
- The spectrum of VUV (MDHL) energy source
- Experimental Configurations

## ■ Results

- Production of  $\text{CN}^-$
- The relations between  $\text{CN}^-$  and  $\text{C}_2\text{H}_6$
- $\text{CN}^-$  formation efficiency of EUV (40.8 eV) and VUV (9.27 eV)

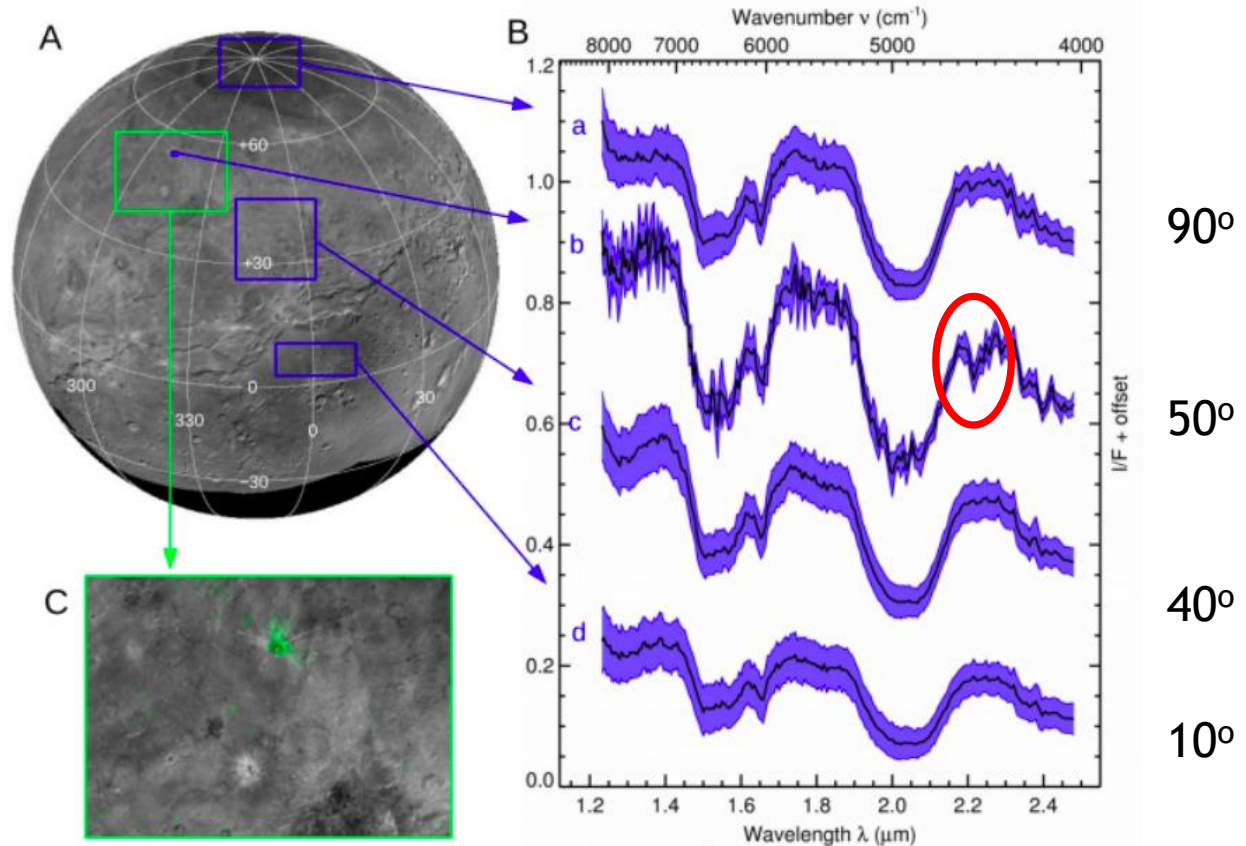

## ■ Astrophysical Implications

- Understand  $\text{CN}^-$  formation after winter on Charon

# Motivation

# Ammonia on Organa Crater

- Ammonia hydrate ( $2.21\mu\text{m}$ ) was detected all over the surfaces, especially on Organa Crater

from Grundy et al. (2016)

# Surface temperatures at different latitudes

- Thermal model from Grundy et al. (2016) shows the pole position is **below 25 K** for 130 years
- **Methane can condense** on those positions where the temperature is below 25 K.

Quoted from Grundy et al. (2016)

# What astrophysical environments are we demonstrating?

Charon in Pluto system

Quoted from Grundy et al. (2017)

# Production mechanism of $CN^-$

Enthalpy of  $CH_3NH_2$  formation

Quoted from Kundu et al. (2017)

Quoted from Kim and Kaiser (2011)

# Production of $CN^-$

- 2 steps/1 step?

2 steps rate equation:

- $[CN^-] = \left(1 + \frac{k_1 e^{-k_2 t}}{k_2 - k_1} - \frac{k_2 e^{-k_1 t}}{k_2 - k_1}\right) [A]_o$

1 step rate equation:

- $[CN^-] = (1 - e^{-kt})[A]_o$

Quoted from Kim and Kaiser (2011)

# Production mechanism of $\text{CN}^-$

- Different results from 2  $e^-$  irradiating experiments
  - *5 keV  $e^-$  by Kim and Kaiser (2011):*
    - The intermediate  $\text{CH}_3\text{NH}_2$  was detected by TPD
  - *1- 90 eV  $e^-$  experiment by Kundu et al.(2017)*
    - The intermediate  $\text{CH}_3\text{NH}_2$  cannot be detected by TPD

# Experimental Protocol:

- 1. To compare with **previous studies**
  - Kim and Kaiser ( $\text{CH}_4:\text{NH}_3$  **3:1**) (5 keV  $\text{e}^-$ )
  - Kundy et al. ( $\text{CH}_4:\text{NH}_3$  **3:2**) (1-90 eV  $\text{e}^-$ )
  - We perform ( $\text{CH}_4:\text{NH}_3$  **3:2**)

**photon** sources: VUV (9.27 eV) and EUV (40.8 eV)
- 2. To simulate the **surface of Charon**
  - Different relative proportion of  **$\text{CH}_4:\text{NH}_3$  1:5, 1:10, 1:20**

# Methodology

# Experimental Configurations

Energetic Source	Constituent	Column Density ( $\times 10^{15}$ molecules $\text{cm}^{-2}$ )			
		3:2	1:5	1:10	1:20
VUV (MDHL)	CH <sub>4</sub>	900	120	60	30
	NH <sub>3</sub>	600	600	600	600
EUV (30.4 nm)	CH <sub>4</sub>	900	120	--	--
	NH <sub>3</sub>	600	600	--	--

Different initial amount of CH<sub>4</sub> correspond to different ratio of CH<sub>4</sub>:NH<sub>3</sub> ice mixtures

# Experimental setup

- ▶ IR path
- ▶ VUV/EUV path

Quoted from Chen et al. (2014)

# Experimental Procedure

KBr substrate is **pre-cooled** to 15 K  
( $1 \times 10^{-10}$  torr) from 300 K ( $8 \times 10^{-10}$  torr)

**Deposit** the ice mixtures through leak valve, with different partial pressures of  $\text{CH}_4$  and  $\text{NH}_3$

**Irradiate** the samples by EUV/VUV

**Warm-up** with 1 K/min

# The spectrum of VUV (MDHL) energy source

- $\text{H}_2$  0.4 torr was adopted
- 19.1% is Ly- $\alpha$
- average photon energy is 9.27 eV
- EUV is 40.8 eV (30.4nm) provided by NSRRC

Quoted from Chen et al. (2014)

# Results

# Beer's Law

Absorbance  $\tau(\nu)$  :

$$\blacksquare \tau(\nu) = -\ln T = -\ln \left( \frac{I(\nu)}{I_0(\nu)} \right) = nl\sigma(\nu)$$

$n$ : number density (molecules  $\text{cm}^{-3}$ )

$l$ : path length (cm)

$\sigma(\nu)$ : cross-section ( $\text{cm}^2$  molecules $^{-1}$ )

Column density  $N$ :

$$\blacksquare N = \frac{\int \tau(\nu) d\nu}{A(\nu)}$$

$A(\nu)$ : absorption strength (A-value) ( $\text{cm molecule}^{-1}$ )

Infra-red spectra before (black lines) and after (coloured lines) VUV irradiation where  $\text{CN}^-$ ,  $\text{C}_2\text{H}_6$  and  $\text{C}_3\text{H}_8$  are formed after VUV irradiation.

# 1. Production of CN<sup>-</sup>

# 1. Production of $CN^-$

■  $[CN^-] = \left(1 + \frac{k_1 e^{-k_2 t}}{k_2 - k_1} - \frac{k_2 e^{-k_1 t}}{k_2 - k_1}\right) [A]_o$

Ratio of $CH_4+NH_3$	A ( $\times 10^{16}$ molecules $cm^{-2}$ )	$k_1$ ( $\times 10^{-18}$ photon $^{-1}$ )	$k_2$ (photon $^{-1}$ )
1:20	$4.75 \pm 0.40$	$0.70 \pm 0.09$	>1
1:10	$4.51 \pm 0.18$	$1.33 \pm 0.13$	>1
1:5	$4.61 \pm 0.18$	$1.93 \pm 0.19$	>1
3:2	$2.24 \pm 0.03$	$8.21 \pm 0.70$	>1

# 1. Production of $\text{CN}^-$

Methylamine  
( $\text{CH}_3\text{NH}_2$ ) with  
 $m/z=31$  is detected  
by QMS

$\text{CN}^-$  is formed via a  
2 step mechanism.

## 2. The scenario for $\text{NH}_3$ dominating ice mixtures

Once  $\text{CH}_4$  becomes  $\text{CH}_3$  radical,  $\text{CH}_3\text{NH}_2$  can be easily formed and hence become  $\text{CN}^-$ .

A diagram of  $\text{CH}_4:\text{NH}_3 = 1:5$

## 2. The scenario for CH<sub>4</sub> dominating ice mixtures

CH<sub>3</sub>NH<sub>2</sub> (formed by CH<sub>3</sub> + NH<sub>2</sub>) has a competing relationship with C<sub>2</sub>H<sub>6</sub> (formed by 2 CH<sub>3</sub>) and C<sub>3</sub>H<sub>8</sub> (formed by CH<sub>2</sub> + C<sub>2</sub>H<sub>6</sub> or C<sub>2</sub>H<sub>4</sub> + CH<sub>4</sub>)

C<sub>2</sub>H<sub>6</sub> can form easier than NH<sub>3</sub> dominating case

A diagram of CH<sub>4</sub>+NH<sub>3</sub> = 3:2

## 2. The relations between $\text{CN}^-$ ( $\text{NH}_3$ dominant) and $\text{C}_2\text{H}_6$ ( $\text{CH}_4$ dominant)

$\text{CH}_4:\text{NH}_3$	$\text{C}_2\text{H}_6$ (ML)	$\text{CN}^-$ (ML)	Ratio of $\text{CN}^-$ to $\text{C}_2\text{H}_6$
3:2 ( $\text{CH}_4$ dominant)	19.1	23	1.2
1:5 ( $\text{NH}_3$ dominant)	4.3	49	11.3

Concentration of  $\text{CN}^-$  is not proportional to initial amount of  $\text{CH}_4$  when  $\text{CH}_4$  is in excess.

### 3. Decay rate of reactants by EUV (40.1 eV) and VUV (9.27 eV)

■ Fitting with  $y = Ae^{-kx} + C$

Ratio of CH <sub>4</sub> +NH <sub>3</sub>	3:2		1:5	
Decay rate k (photons <sup>-1</sup> cm <sup>2</sup> )	CH <sub>4</sub> (x 10 <sup>-18</sup> )	NH <sub>3</sub> (x10 <sup>-18</sup> )	CH <sub>4</sub> (x 10 <sup>-18</sup> )	NH <sub>3</sub> (x10 <sup>-18</sup> )
VUV (MDHL)	3.70±0.18	2.89±0.10	2.70±0.07	1.17±0.12
EUV (30.4nm)	0.61±0.03	0.91±0.11	0.49±0.02	0.56±0.06
Ratio of k (VUV to EUV)	6.06±0.07	3.18±0.12	5.52±0.07	2.07±0.13

### 3. Formation rate of $\text{CN}^-$ by EUV (40.1 eV) and VUV (9.27 eV)

$\text{CN}^-$ production rate $k$ ( $\text{photon}^{-1}\text{cm}^2$ )	$\text{CH}_4 : \text{NH}_3$ 3:2 ( $\times 10^{-18}$ )	$\text{CH}_4 : \text{NH}_3$ 1:5 ( $\times 10^{-18}$ )
VUV (MDHL)	$8.21 \pm 0.70$	$1.93 \pm 0.19$
EUV (30.4nm)	$1.92 \pm 1.99$	$0.63 \pm 0.37$
Ratio of $k$ (VUV to EUV) ( $\text{CN}^-$ )	4.28	3.06

### 3. Energy needed for forming radicals by EUV (40.1 eV) and VUV (9.27 eV)

Radicals species	CH <sub>4</sub>	NH <sub>3</sub>
- 1 H	4.55 eV	4.67 eV
-2 H	4.78 eV	4.38 eV
-3 H	9.19 eV	7.63 eV

Quoted from Kundu et al. (2017)

# Combined results

Ratio of k (VUV to EUV) ( $\text{CN}^-$ )	4.28	3.06
Ratio of k (VUV to EUV) ( $\text{CH}_4$ )	$6.06 \pm 0.07$	$5.52 \pm 0.07$
Ratio of k (VUV to EUV) ( $\text{NH}_3$ )	$3.18 \pm 0.12$	$2.07 \pm 0.13$

The **reduced destruction cross-section** of EUV (30.4nm) irradiation is the main factor of reducing the formation rate of  $\text{CN}^-$ .

# Astrophysical Implications

# Estimate the column density of CN<sup>-</sup> formed after winter on Charon (from result 2)

Ly- $\alpha$  flux:  $1.9 \times 10^9 \text{ eV cm}^{-2} \text{ s}^{-1}$

(Grundy et al. 2016)

→ photon dose after 1 Pluto winter

$7.64 \times 10^{17} \text{ photons cm}^{-2}$

CH<sub>4</sub> after winter ~173 ML

Assume the column density of NH<sub>3</sub> is 600 ML

CH <sub>4</sub> :NH <sub>3</sub>	CH <sub>4</sub> (ML)	CN <sup>-</sup> (ML)
1:5	120	36.6
1:10	60	29.5
1:20	30	18.9
3:2	900	22.5

# Ly- $\alpha$ is the main photon source to produce CN<sup>-</sup> on Charon (from result 3)

- VUV(19.1% of which is Ly- $\alpha$ ) will produce CN<sup>-</sup> **3.06 - 4.28 times more efficient** than EUV
- It is expected that Ly-  $\alpha$  will produce CN<sup>-</sup> more efficient than EUV
- Ly-  $\alpha$  flux is **1 order of magnitude** more intense than EUV irradiations at 39.1 A.U. (Grundy et al. 2016)
  - Ly- $\alpha$  flux:  $1.9 \times 10^9 \text{ eV cm}^{-2} \text{ s}^{-1}$
  - EUV flux:  $8.7 \times 10^7 \text{ eV cm}^{-2} \text{ s}^{-1}$

# Conclusion

- 1. Detection of methylamine implies that  $\text{CN}^-$  is formed via a 2 step mechanism.
- 2. Formation of  $\text{CN}^-$  is not proportional to the initial column density of  $\text{CH}_4$  when  $\text{CH}_4$  is in excess.
  - This implies that we have to experimentally estimate the column density of  $\text{CN}^-$  after Charon winter for further investigations.
- 3. The reduced destruction cross-section of EUV (30.4nm) irradiation is the main factor of reducing the formation rate of  $\text{CN}^-$ .
  - This implies that Ly- $\alpha$  (VUV) is the main photon source to produce  $\text{CN}^-$  on Charon.

# Q & A

# Production yield and production rates

- The yields should be correlated with initial limiting substances
- Fitting rates are the same
