Motivation

Motivation

- *CN⁻ formation mechanisms*
 - Different results from 2 groups by electron irradiation at 10-15 K
 - We perform 3:2 CH₄+NH₃ ice mixtures by VUV and EUV photons
- *What astrophysical environments are we demonstrating?*
 - NH₃ : Infra-red spectra shows ammonia on Organa Crater
 - CH₄ : Surface temperatures at different latitudes
 - We perform 1:5 , 1:10 and 1:20 CH₄+NH₃ ice mixtures

Production mechanism of CN^-

Enthalpy of CH_3NH_2 formation

Quoted from Kundu et al. (2017)

Quoted from Kim and Kaiser (2011)

Production of CN^-

- 2 steps/1 step?

2 steps rate equation:

$$[CN^-] = \left(1 + \frac{k_1 e^{-k_2 t}}{k_2 - k_1} - \frac{k_2 e^{-k_1 t}}{k_2 - k_1}\right) [A]_o$$

1 step rate equation:

$$[CN^-] = (1 + e^{-kt}) [A]_o$$

Quoted from Kim and Kaiser (2011)

Production mechanism of CN^-

Attempts to detect CH_3NH_2 :

- Different results from 2 e^- irradiating experiments
 - 5 keV e^- by Kim and Kaiser (2011):
 - The intermediate CH_3NH_2 was detected by TPD
 - 1- 90 eV e^- experiment by Kundu et al.(2017)
 - The intermediate CH_3NH_2 cannot be detected by TPD
- How about EUV and VUV photons?

What astrophysical environments are we demonstrating?

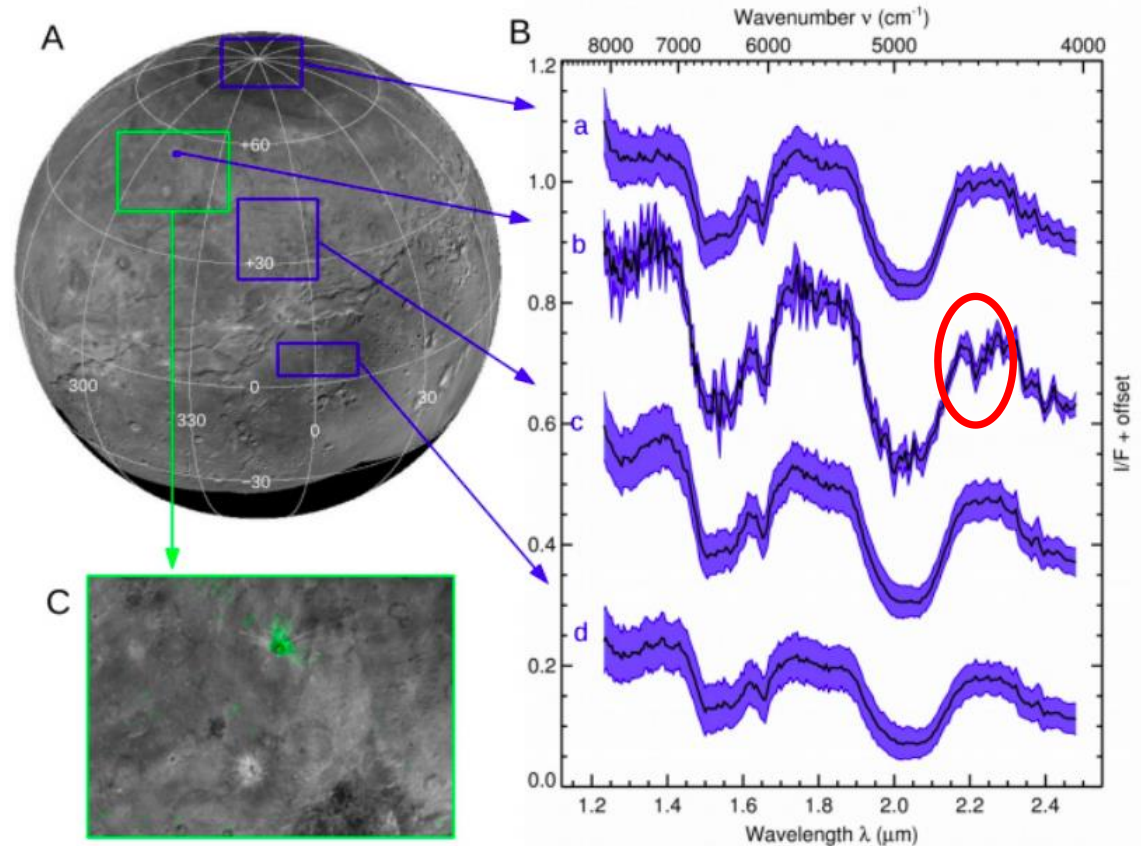

Charon in Pluto system

Quoted from Grundy et al.
(2017)

Ammonia on Organa Crater

- *Ammonia* hydrate ($2.21\mu\text{m}$) was detected all over the surfaces, especially on Organa Crater

from Grundy et al. (2016)

Surface temperatures at different latitudes

- Thermal model from Grundy et al. (2016) shows the pole position is **below 25 K** for 130 years
- **Methane can condense** on those positions where the temperature is below 25 K.

Quoted from Grundy et al. (2016)

Short Summary

- 1. To compare with **previous studies**
 - *Kim and Kaiser ($\text{CH}_4:\text{NH}_3$ **3:1**) and Kundy et al. (2017) ($\text{CH}_4:\text{NH}_3$ **3:2**)*
 - *We perform experiment of **$\text{CH}_4+\text{NH}_3 = 3:2$***
 - *Confirm the mechanism of CN^-*
- 2. To simulate the **surface of Charon**
 - *Experiment: **$\text{CH}_4:\text{NH}_3 = 1:5, 1:10, 1:20$***
 - *Variation of photon sources: from VUV to EUV*

Methodology

Experimental setup

Quoted from Chen et al. (2014)

Experimental Protocol

KBr substrate is **pre-cooled** to 15 K (1×10^{-10} torr) from 300 K (8×10^{-10} torr)

Deposit the ice mixtures through leak valve, with different partial pressures of CH_4 and NH_3

Irradiate the samples by EUV/VUV

Warm-up with 1 K/min

The spectrum of VUV (MDHL) energy source

- H₂ 0.4 torr was adopted
- 19.1% is Ly- α
- average photon energy is 9.27 eV
- EUV is 40.8 eV (30.4nm) provided by NSRRC

Quoted from Chen et al. (2014)

Experimental Configurations

Energetic Source	constituent	Column Density ($\times 10^{15}$ molecules cm^{-2})			
		3:2	1:5	1:10	1:20
VUV (MDHL)	CH ₄	900	120	60	30
	NH ₃	600	600	600	600
EUV (30.4 nm)	CH ₄	900	120	--	--
	NH ₃	600	600	--	--

Results

Beer's Law

Transmittance $T(\nu)$ is defined by:

$$\blacksquare \quad T(\nu) = \frac{I(\nu)}{I_o(\nu)}$$

Absorbance $\tau(\nu)$ is defined by:

$$\blacksquare \quad \tau(\nu) = -\ln T = -\ln \left(\frac{I(\nu)}{I_o(\nu)} \right) = n l \sigma(\nu)$$

- where n is number density (molecules cm^{-3}), l is the path length (cm) and $\sigma(\nu)$ is the cross-section ($\text{cm}^2 \text{ molecules}^{-1}$)

Column density N is defined by:

$$\blacksquare \quad N = \frac{\int \tau(\nu) d\nu}{A(\nu)}$$

- where N is column density (molecules cm^{-2}), $A(\nu)$ is the absorption strength (A -value) (cm molecule^{-1}) from literatures

Infra-red spectra before (black lines) and after (coloured lines) VUV irradiation where CN^- , C_2H_6 and C_3H_8 are formed after VUV irradiation.

1. Production of CN⁻

■ $[CN^-] = \left(1 + \frac{k_1 e^{-k_2 t}}{k_2 - k_1} - \frac{k_2 e^{-k_1 t}}{k_2 - k_1}\right) [A]_o$

Table 3.5: The fitting results of CN⁻ by equation 2.10

VUV experiments with CH ₄ +NH ₃ ice mixtures			
Ratio	A (x10 ¹⁶ molecules cm ⁻²)	k ₁ (x10 ⁻¹⁸ photon ⁻¹)	k ₂ (photon ⁻¹)
1:20	4.75 ± 0.40	0.70 ± 0.09	>1
1:10	4.51 ± 0.18	1.33 ± 0.13	>1
1:5	4.61 ± 0.18	1.93 ± 0.19	>1
3:2	2.24 ± 0.03	8.21 ± 0.70	>1
Quotated from Kim and Kaiser[2]			
Ratio	A(x10 ¹⁶ molecules cm ⁻²)	k ₁ (× 10 ⁻³ s ⁻¹)	k ₂ (× 10 ⁻³ s ⁻¹)
0.1 μA e ⁻ with CH ₄ +NH ₃ ice mixtures			
3:1	1.3 ± 0.0	2.7 ± 0.3	8.9 ± 1.6
1 μA e ⁻ with C _n H _{2n+2} (n=1-6)+NH ₃ ice mixtures			
2:5	1.0 ± 0.0	8.7 ± 1.3	»1

A represents the amount of CN⁻ we may obtain when irradiated the ice for infinitely long.

1. Production of CN⁻

1. Production of CN^-

Methylamine
(CH_3NH_2) with
 $m/z=31$ is
detected by QMS

2. The scenario for NH_3 dominating ice mixtures

Once CH_4 becomes CH_3 radical, it can easily form CH_3NH_2 and hence become CN^- .

A diagram of $\text{CH}_4:\text{NH}_3 = 1:5$

2. The scenario for CH_4 dominating ice mixtures

CH_2NH_3 (formed by CH_3 + NH_2) has a competing relationship with C_2H_6 (formed by 2 CH_3) and C_3H_8 (formed by CH_2 + C_2H_6 or C_2H_4 + CH_4)

A diagram of $\text{CH}_4 + \text{NH}_3 = 3:2$

2. The relations between CN^- and C_2H_6 during VUV irradiations

$\text{CH}_4:\text{NH}_3$	C_2H_6 (ML)	CN^- (ML)	Ratio of CN^- to C_2H_6
3:2 (CH_4 dominant)	19.1	23	1.2
1:5 (NH_3 dominant)	4.3	49	11.3

Concentration of CN^- is not proportional to initial amount of CH_4 when CH_4 is in excess.

3. Energy needed for forming radicals by EUV (40.1 eV) and VUV (9.27 eV)

Radicals species	CH ₄	NH ₃
- 1 H	4.55 eV	4.67 eV
-2 H	4.78 eV	4.38 eV
-3 H	9.19 eV	7.63 eV

(quoted from Kundu et al. (2017))

3. Destruction cross-section of EUV (40.1 eV) and VUV (9.27 eV)

■ Fitting with $y = Ae^{-kx} + C$ (pseudo first order kinetics)

3. CN⁻ formation efficiency of EUV (40.1 eV) and VUV (9.27 eV)

k (photons ⁻¹ cm ²)	CH ₄ (x 10 ⁻¹⁸)	NH ₃ (x10 ⁻¹⁸)
VUV (MDHL)	3.70±0.18	2.89±0.10
EUV (30.4nm)	0.61±0.03	0.91±0.11
Destruction cross-section ratio	6.06±0.07	3.18±0.12
k (photon ⁻¹ cm ²)	CH ₄ to NH ₃ 3:2 (x 10 ⁻¹⁸)	CH ₄ to NH ₃ 1:5 (x10 ⁻¹⁸)
VUV (MDHL)	8.21±0.70	1.93±0.19
EUV (30.4nm)	1.92±1.99	0.63±0.37
CN⁻ production ratio	4.28	3.06

Astrophysical implications

Understand CN⁻ formation after winter on surface of Charon

Surface composition after 1 Pluto winter:

■ Ly α exposure: $1.9 \times 10^9 \text{ eV cm}^{-2} \text{ s}^{-1}$
(Grundy et al. 2016)

→ photon dose: $7.64 \times 10^{17} \text{ photons cm}^{-2}$

■ CH₄ deposition rate:
(Hoey et al. 2017)

→ ~110-150 ML in 130 earth years

CH ₄ +NH ₃ 3	CH ₄ (ML)	CN ⁻ (ML)
1:5	110	36.6
1:10	60	29.5
1:20	30	18.9
3:2	900	22.5

Astrophysical implications

- VUV is 3.06 to 4.28 times more efficient than EUV
- VUV flux is 1 order of magnitude more intense than EUV irradiations (Grundy et al. 2016)
- Ly- α exposure: $1.9 \times 10^9 \text{ eV cm}^{-2} \text{ s}^{-1}$
- EUV exposure: $8.7 \times 10^7 \text{ eV cm}^{-2} \text{ s}^{-1}$

Ly- α is the main energy source to produce CN^- on Charon

Conclusion

- 1. Detection of methylamine implies that CN^- is formed via a 2 step mechanism.
- 2. Concentration of CN^- is not proportional to the initial amount of CH_4 when CH_4 is in excess.
 - *This implies that we have to experimentally simulate the amount of CN^- after Charon winter for further investigations.*
- 3. The reduced destruction cross-section of EUV 30.4nm irradiation is the main factor of slowing the rate of formations.
 - *This implies that Ly-a is the main energy source to produce CN^- on Charon.*

Q & A

Production yield and production rates

- The yields should be correlated with initial limiting substances
- Fitting rates are the same
